0.1 Analyze A/B Test Results

You may either submit your notebook through the workspace here, or you may work from your local machine and submit through the next page. Either way assure that your code passes the project RUBRIC. Please save regularly.

This project will assure you have mastered the subjects covered in the statistics lessons. The hope is to have this project be as comprehensive of these topics as possible. Good luck!

0.2 Table of Contents

Introduction

A/B tests are very commonly performed by data analysts and data scientists. It is important that you get some practice working with the difficulties of these

For this project, you will be working to understand the results of an A/B test run by an ecommerce website. Your goal is to work through this notebook to help the company understand if they should implement the new page, keep the old page, or perhaps run the experiment longer to make their decision.

As you work through this notebook, follow along in the classroom and answer the corresponding quiz questions associated with each question. The labels for each classroom concept are provided for each question. This will assure you are on the right track as you work through the project, and you can feel more confident in your final submission meeting the criteria. As a final check, assure you meet all the criteria on the RUBRIC.

Part I - Probability

To get started, let's import our libraries.

```
In [44]: import pandas as pd
    import numpy as np
    import random
    import matplotlib.pyplot as plt
    %matplotlib inline
    #We are setting the seed to assure you get the same answers on quizzes as we set up
    random.seed(42)
```

- 1. Now, read in the ab_data.csv data. Store it in df. Use your dataframe to answer the questions in Quiz 1 of the classroom.
 - a. Read in the dataset and take a look at the top few rows here:

```
In [45]: df = pd.read_csv('ab_data.csv')
        df.head()
Out [45]:
           user_id
                                      timestamp
                                                     group landing_page converted
            851104 2017-01-21 22:11:48.556739
        0
                                                   control
                                                               old_page
                                                                                 0
         1

                                                               new_page
                                                                                 0
            864975 2017-01-21 01:52:26.210827
         4
                                                                                 1
                                                   control
                                                               old_page
```

b. Use the cell below to find the number of rows in the dataset.

```
In [46]: df shape
Out[46]: (294478, 5)
```

c. The number of unique users in the dataset.

d. The proportion of users converted.

```
In [48]: df.converted.mean()
Out[48]: 0.11965919355605512
```

e. The number of times the new_page and treatment don't match.

```
In [49]: df.query('landing_page == "new_page" & group == "control"').shape[0] + df.query('landing_page == "new_page" & group == "new_page" & group == "new_page == "new_page" & group == "ne
```

f. Do any of the rows have missing values?

- 2. For the rows where **treatment** does not match with **new_page** or **control** does not match with **old_page**, we cannot be sure if this row truly received the new or old page. Use **Quiz 2** in the classroom to figure out how we should handle these rows.
 - a. Now use the answer to the quiz to create a new dataset that meets the specifications from the quiz. Store your new dataframe in **df2**.

```
In [51]: df2 = df[((df['group'] == 'treatment') == True) == ((df['landing_page'] == 'new_page')
        df2.head()
Out [51]:
            user_id
                                                     group landing_page converted
                                      timestamp
            851104 2017-01-21 22:11:48.556739
                                                   control
                                                               old_page
            804228 2017-01-12 08:01:45.159739
                                                               old_page
                                                   control
                                                                                 0
           661590 2017-01-11 16:55:06.154213 treatment
                                                               new_page
                                                                                 0
            853541 2017-01-08 18:28:03.143765 treatment
                                                               new_page
         3
                                                                                 0
            864975 2017-01-21 01:52:26.210827
                                                               old_page
                                                   control
In [52]: # Double Check all of the correct rows were removed - this should be 0
         df2[((df2['group'] == 'treatment') == (df2['landing_page'] == 'new_page')) == False].sh
Out[52]: 0
```

- 3. Use df2 and the cells below to answer questions for Quiz3 in the classroom.
- a. How many unique user_ids are in df2?

```
In [53]: df2.user_id.nunique()
Out[53]: 290584
```

b. There is one **user_id** repeated in **df2**. What is it?

c. What is the row information for the repeat **user_id**?

```
In [55]: #2893
```

d. Remove **one** of the rows with a duplicate **user_id**, but keep your dataframe as **df2**.

```
In [58]: df shape
Out[58]: (294478, 5)
```

- 4. Use df2 in the cells below to answer the quiz questions related to Quiz 4 in the classroom.
- a. What is the probability of an individual converting regardless of the page they receive?

```
In [59]: df2.converted.mean()
Out[59]: 0.11959708724499628
```

Out [63]: -0.0014795997940775518

b. Given that an individual was in the control group, what is the probability they converted?

```
In [60]: df2.query('group == \"control\"')['converted'].mean()
Out[60]: 0.1203863045004612
```

c. Given that an individual was in the treatment group, what is the probability they converted?

```
In [61]: df2.query('group == \"treatment\"')['converted'].mean()
Out[61]: 0.11880806551510564
```

d. What is the probability that an individual received the new page?

```
In [62]: df2.query('landing_page == "new_page"').shape[0] / df2.shape[0]
Out[62]: 0.5000619442226688
In [63]: obs_diff = np.mean(df.query('group == "treatment"')['converted']) - np.mean(df.query('group obs_diff))
```

e. Consider your results from parts (a) through (d) above, and explain below whether you think there is sufficient evidence to conclude that the new treatment page leads to more conversions.

My observations suggest that the control group, which viewed the old page, was more likely to convert than the treatment group. but we need more investigations to be conducted to conclude the evidence. ### Part II - A/B Test

Notice that because of the time stamp associated with each event, you could technically run a hypothesis test continuously as each observation was observed.

However, then the hard question is do you stop as soon as one page is considered significantly better than another or does it need to happen consistently for a certain amount of time? How long do you run to render a decision that neither page is better than another?

These questions are the difficult parts associated with A/B tests in general.

1. For now, consider you need to make the decision just based on all the data provided. If you want to assume that the old page is better unless the new page proves to be definitely better at a Type I error rate of 5%, what should your null and alternative hypotheses be? You can state your hypothesis in terms of words or in terms of p_{old} and p_{new} , which are the converted rates for the old and new pages.

```
0.2.1 H0: <= 0.2.2 H1: >
```

2. Assume under the null hypothesis, p_{new} and p_{old} both have "true" success rates equal to the **converted** success rate regardless of page - that is p_{new} and p_{old} are equal. Furthermore, assume they are equal to the **converted** rate in **ab_data.csv** regardless of the page.

Use a sample size for each page equal to the ones in **ab_data.csv**.

Perform the sampling distribution for the difference in **converted** between the two pages over 10,000 iterations of calculating an estimate from the null.

Use the cells below to provide the necessary parts of this simulation. If this doesn't make complete sense right now, don't worry - you are going to work through the problems below to complete this problem. You can use **Quiz 5** in the classroom to make sure you are on the right track.

a. What is the **conversion rate** for p_{new} under the null?

b. What is the **conversion rate** for p_{old} under the null?

```
In [65]: p_null
Out[65]: 0.11959708724499628
```

c. What is n_{new} , the number of individuals in the treatment group?

d. What is n_{old} , the number of individuals in the control group?

e. Simulate n_{new} transactions with a conversion rate of p_{new} under the null. Store these n_{new} 1's and 0's in **new_page_converted**.

f. Simulate n_{old} transactions with a conversion rate of p_{old} under the null. Store these n_{old} 1's and 0's in **old_page_converted**.

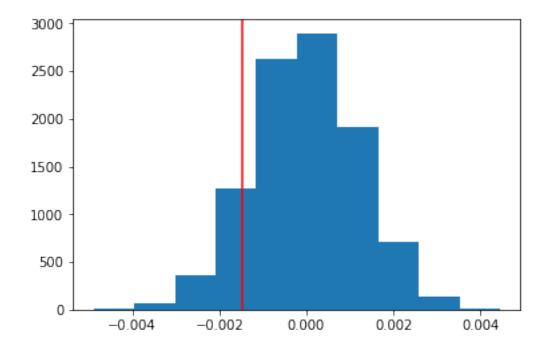

g. Find p_{new} - p_{old} for your simulated values from part (e) and (f).

```
In [70]: new_page_converted.mean() - old_page_converted.mean()
Out[70]: -0.0006008115218738147
```

h. Create 10,000 p_{new} - p_{old} values using the same simulation process you used in parts (a) through (g) above. Store all 10,000 values in a NumPy array called **p_diffs**.

i. Plot a histogram of the **p_diffs**. Does this plot look like what you expected? Use the matching problem in the classroom to assure you fully understand what was computed here.

Out[72]: <matplotlib.lines.Line2D at 0x7ffb730b1cc0>

j. What proportion of the **p_diffs** are greater than the actual difference observed in **ab_data.csv**?

```
In [73]: np.mean(p_diffs > obs_diff)
Out[73]: 0.88629999999999999
```

k. Please explain using the vocabulary you've learned in this course what you just computed in part **j**. What is this value called in scientific studies? What does this value mean in terms of whether or not there is a difference between the new and old pages?

The value of 0.89 is called the p-value. This value indicates in which extend the null hypothisis can be assumed to be true. our p-value needs to be less than 0.05 in order to rightfully reject the null hypothisis.

However, it appears that the p-value is above 0.05, which means we do not have evidence to reject the null hypothesis.

I. We could also use a built-in to achieve similar results. Though using the built-in might be easier to code, the above portions are a walkthrough of the ideas that are critical to correctly thinking about statistical significance. Fill in the below to calculate the number of conversions for each page, as well as the number of individuals who received each page. Let n_old and n_new refer the the number of rows associated with the old page and new pages, respectively.

```
In [74]: import statsmodels.api as sm

convert_old = df2.query('landing_page == "old_page" & converted == 1').shape[0]
    convert_new = df2.query('landing_page == "new_page" & converted == 1').shape[0]
    n_old = df2.query('landing_page == "old_page"').shape[0]
    n_new = df2.query('landing_page == "new_page"').shape[0]
```

m. Now use stats.proportions_ztest to compute your test statistic and p-value. Here is a helpful link on using the built in.

1.31092419842 0.189883374482

n. What do the z-score and p-value you computed in the previous question mean for the conversion rates of the old and new pages? Do they agree with the findings in parts j. and k.?

The z-score here is (1.31092419842) so it's indicates how many standard deviations an element is from the mean. The p-score here is (0.189883374482) so it's the confidence level for our null hypothesis.which is not below our alpha of 0.05. so the z-test appears to agree with the previous findings. ### Part III - A regression approach

- 1. In this final part, you will see that the result you achieved in the A/B test in Part II above can also be achieved by performing regression.
 - a. Since each row is either a conversion or no conversion, what type of regression should you be performing in this case?

In this case: a logical regression is to be performed.

b. The goal is to use **statsmodels** to fit the regression model you specified in part **a.** to see if there is a significant difference in conversion based on which page a customer receives. However, you first need to create in df2 a column for the intercept, and create a dummy variable column for which page each user received. Add an **intercept** column, as well as an **ab_page** column, which is 1 when an individual receives the **treatment** and 0 if **control**.

```
In [76]: df2['intercept'] = 1
        df2[['aPage', 'ab_page']] = pd.get_dummies(df2['group'])
         df2 = df2.drop('aPage', axis=1)
         df2.head()
Out[76]:
           user_id
                                                    group landing_page converted
                                     timestamp
         0
            851104 2017-01-21 22:11:48.556739
                                                  control
                                                              old_page
                                                                                0
            804228 2017-01-12 08:01:45.159739
         1
                                                  control
                                                              old_page
                                                                                0
         2
          661590 2017-01-11 16:55:06.154213 treatment
                                                              new_page
                                                                                0
         3
            853541 2017-01-08 18:28:03.143765 treatment
                                                              new_page
                                                                                0
            864975 2017-01-21 01:52:26.210827
                                                              old_page
                                                  control
                                                                                1
           intercept ab_page
         0
                   1
         1
                            0
         2
                   1
                            1
         3
                   1
                            1
                   1
                            0
```

c. Use **statsmodels** to instantiate your regression model on the two columns you created in part b., then fit the model using the two columns you created in part b. to predict whether or not an individual converts.

d. Provide the summary of your model below, and use it as necessary to answer the following questions.

e. What is the p-value associated with ab_page? Why does it differ from the value you found in Part II? Hint: What are the null and alternative hypotheses associated with your regression model, and how do they compare to the null and alternative hypotheses in Part II?

The p-value associated with ab_page is (0.190). The logistic regression suggests that users on the old page are about 1.015 more likely to convert on average than users on the new page. so the old page would be better than the new page in terms of conversion rates.

f. Now, you are considering other things that might influence whether or not an individual converts. Discuss why it is a good idea to consider other factors to add into your regression model. Are there any disadvantages to adding additional terms into your regression model?

I don't see that the treatment has much impact on whether a user converts, So it is probably a good idea to see whether other factors might predict conversion. And i think adding more variables to the regression model it will benefit us more.

g. Now along with testing if the conversion rate changes for different pages, also add an effect based on which country a user lives in. You will need to read in the **countries.csv** dataset and merge together your datasets on the appropriate rows. Here are the docs for joining tables.

Does it appear that country had an impact on conversion? Don't forget to create dummy variables for these country columns - **Hint: You will need two columns for the three dummy variables.** Provide the statistical output as well as a written response to answer this question.

```
In [79]: countries = pd.read_csv('countries.csv')
       countries.head()
Out[79]:
         user_id country
          834778
                   UK
       1
          928468
                   US
       2
          822059
                   UK

h. Though you have now looked at the individual factors of country and page on conversion, we would now like to look at an interaction between page and country to see if there significant effects on conversion. Create the necessary additional columns, and fit the new model.

Provide the summary results, and your conclusions based on the results.

```
In [84]: lm = sm.Logit(df2['ab_page'], df2[['intercept', 'CA', 'UK']])
       result = lm.fit()
       result.summary2()

Finishing Up

Congratulations! You have reached the end of the A/B Test Results project! You should be very proud of all you have accomplished!

Tip: Once you are satisfied with your work here, check over your report to make sure that it is satisfies all the areas of the rubric (found on the project submission page at the end of the lesson). You should also probably remove all of the "Tips" like this one so that the presentation is as polished as possible.

0.3 Directions to Submit

Before you submit your project, you need to create a .html or .pdf version of this note-book in the workspace here. To do that, run the code cell below. If it worked correctly,

you should get a return code of 0, and you should see the generated .html file in the workspace directory (click on the orange Jupyter icon in the upper left).

Alternatively, you can download this report as .html via the **File > Download as** submenu, and then manually upload it into the workspace directory by clicking on the orange Jupyter icon in the upper left, then using the Upload button.

Once you've done this, you can submit your project by clicking on the "Submit Project" button in the lower right here. This will create and submit a zip file with this .ipynb doc and the .html or .pdf version you created. Congratulations!
